

## Figure Legends

1. The geometry of the model RyR pore. In the experiments and calculations, the lumen of the sarcoplasmic reticulum (SR) is electrically grounded. The circle around each labeled amino acid is meant to illustrate the range of the motion of the terminal carboxyl group. Aspartates (solid circles) are given a radius of 5 Å and glutamates (dashed circles) 7 Å. Only the amino acids of one of the four identical RyR subunits is shown. Asp-4945, Asp-4938, Asp-4899, Glu-4900, and Glu-4902 are the only amino acids explicitly modeled in the theory. The GGGIG sequence (4894-4898 in the numbering) at the cytosolic end of the selectivity filter is only a reference point for readers familiar with the RyR sequence.
2. Experimental verification of the AMFE predicted by the theory. The lines are the theory and the symbols are the experimental data with standard error bars and the number of experiments in parentheses. The solid line and symbols are the addition of  $\text{Ca}^{2+}$  to  $\text{Na}^+$  and the dashed line and open symbols are the addition of  $\text{Ca}^{2+}$  to  $\text{Cs}^+$ . In all cases, the monovalent-chloride concentration was 100 mM in both cytosolic and luminal baths and the indicated amount  $\text{Ca}^{2+}$  was added to the luminal bath. The current at  $-20$  mV is shown.
3. The partitioning coefficient of  $\text{K}^+$  (panel A) and  $\text{Ca}^{2+}$  (panel B) plotted logarithmically.  $[\text{K}^+] = 150$  mM and the indicated  $[\text{Ca}^{2+}]$  is in both baths.
4. The electrostatic component of partitioning  $z_i e \phi(x) / kT$  of  $\text{K}^+$  (panel A) and  $\text{Ca}^{2+}$  (panel B) in the pore.  $[\text{K}^+] = 150$  mM and the indicated  $[\text{Ca}^{2+}]$  is in both baths.
5. The screening component of partitioning  $\Delta\mu_i^{\text{SC}}(x) / kT$  of  $\text{K}^+$  (solid lines) and  $\text{Ca}^{2+}$  (dashed lines) in the pore.  $[\text{K}^+] = 150$  mM and  $[\text{Ca}^{2+}]$  is changed from 1  $\mu\text{M}$  to 50 mM. Because the curves are so close together,  $[\text{Ca}^{2+}]$  is not indicated.
6. The excluded-volume (hard-sphere) component of partitioning  $\Delta\mu_i^{\text{HS}}(x) / kT$  of  $\text{K}^+$  (solid lines) and  $\text{Ca}^{2+}$  (dashed lines) in the pore.  $[\text{K}^+] = 150$  mM and  $[\text{Ca}^{2+}]$  is changed from 1  $\mu\text{M}$  to 50 mM. Because the curves are so close together,  $[\text{Ca}^{2+}]$  is not indicated.
7. Components of the binding selectivity from Eq. (8) in the selectivity filter at  $x = 20$  Å in Fig. 1.  $[\text{K}^+] = 150$  mM and the indicated  $[\text{Ca}^{2+}]$  is in both baths. The horizontal-hatched bar is the number advantage, the diagonal-hatched bar is the mean electrostatic advantage, the cross-hatched bar is the screening advantage, and the solid bar is the excluded-volume advantage. The horizontal line is the binding selectivity of Eq. (8) (i.e., the sum of all the terms). A positive term favors the binding of  $\text{Ca}^{2+}$  while a negative term favors  $\text{K}^+$ .
8. Concentration profiles in the pore of the monovalent cation (panel A) and  $\text{Ca}^{2+}$  (panel B). For each indicated monovalent cation  $\text{X}^+$ ,  $[\text{X}^+] = 150$  mM and  $[\text{Ca}^{2+}] = 1$  mM in both baths.
9. Components of the binding selectivity from Eq. (8) in the selectivity filter at  $x = 20$  Å in Fig. 1. For each indicated monovalent cation  $\text{X}^+$ ,  $[\text{X}^+] = 150$  mM and  $[\text{Ca}^{2+}] = 1$  mM in both baths. Ion diameters:  $\text{Li}^+$  1.33 Å;  $\text{Na}^+$  2.00 Å;  $\text{K}^+$  2.76 Å;  $\text{Cs}^+$  3.40 Å. The horizontal-hatched bar is the number advantage, the diagonal-hatched bar is the mean electrostatic advantage, the cross-hatched bar is the screening advantage, and the solid bar is the excluded-volume advantage. The

- horizontal line is the binding selectivity of Eq. (8) (i.e., the sum of all the terms). A positive term favors the binding of  $\text{Ca}^{2+}$  while a negative term favors  $\text{K}^+$ .
10. Concentration profiles in the pore for the mutations D4899N (panels A and B) and D4938N (panels C and D) for  $\text{K}^+$  (panels A and C) and  $\text{Ca}^{2+}$  (panels B and D). The profiles for native (WT) channel are the solid lines and for the mutations the dashed lines.  $[\text{K}^+] = 150 \text{ mM}$  and  $[\text{Ca}^{2+}] = 1 \text{ mM}$  in both baths. In the model, the mutation is created by “turning off” the charge on the four Asp-4899 or the four Asp-4939. The mutation site is the region from which the charge has been removed.
  11. Profiles of the binding selectivity from Eq. (8) (panel A) and its components (excluded volume, panel B; mean electrostatic, panel C; screening, panel D) for the native (WT) channel (solid line) and the mutation D4899N (dashed line). The conditions are those described in Fig. 10.
  12. Profiles of the binding selectivity from Eq. (8) (panel A) and its components (excluded volume, panel B; mean electrostatic, panel C; screening, panel D) for the native (WT) channel (solid line) and the mutation D4938N (dashed line). The conditions are those described in Fig. 10.
  13. (A-H) Current/voltage curves in KCl. (I) The conductance at reversal potential with cytosolic  $[\text{K}^+]$  is held at 250 mM and luminal  $[\text{K}^+]$  is varied. For both experiment and theory the current/voltage was fitted with a line and the slope is plotted. In this and the following figures, concentrations are listed as cytosolic | luminal. The solid lines are the model and symbols are the experimental data. Comparing panel I and Fig. 16B of Ref. 20 summarizes the improvements due to the new RyR model; in general the computed current/voltage curves are more linear and the conductances are significantly closer to experimental values, especially in cases where the luminal concentration is low. With the exception of panel F, this experimental data was previously published by Chen et al. (17). The data in panel F was previously published by Gillespie et al. (20).
  14. Current/voltage curves of (A) native (WT) RyR ( $\times$ ) and the mutants D4899N ( $\blacksquare$ ) and E4900Q ( $\square$ ) and (B) the D4938N mutant in 250 mM symmetric KCl. The D4899N data was previously published by Gao et al. (7), E4900Q by Wang et al. (42), and D4938N by Xu et al. (43).
  15. Current/voltage curves in LiCl. The dashed line is the model result for 250 mM cytosolic and 25 mM luminal bath concentrations ( $\Delta$ ). Compared to the previous model, the dashed line reproduces the data much better. This experimental data was previously published by Chen et al. (18).
  16. Current/voltage curves in NaCl. Compared to the previous model, the current/voltage curves are more linear and reproduce the data better in very asymmetric solutions. This experimental data was previously published by Chen et al. (18).
  17. Current/voltage curves in RbCl. Compared to the previous model, the current/voltage curves are more linear and reproduce the data better in very asymmetric solutions. This experimental data was previously published by Chen et al. (18).
  18. Current/voltage curves in CsCl. Compared to the previous model, the current/voltage curves are more linear and reproduce the data better in very

- asymmetric solutions. This experimental data was previously published by Chen et al. (18).
19. Mole fraction experiments at 250 mM total cation concentration in symmetric solutions. (A) NaCl and CsCl mixtures. The experimental point at mole fraction 0.6 is statistically significantly different than the point at mole fraction 1 ( $p < 0.05$ ). The number of experiments is shown in parentheses. This experimental data was previously published by Gillespie et al. (20), but this is the first publication of this data with the multiple experiments. (B) LiCl and KCl mixtures. This experimental data at these concentrations was previously published by Chen et al. (18). This mole fraction experiment was first performed at 210 mM total cation concentration by Lindsay et al. (50).
  20. Current/voltage curves in bi-ionic conditions. This experimental data was previously published by Chen et al. (18).
  21. Current/voltage curves with divalent and monovalent cations. (A) KCl and CaCl<sub>2</sub>. (B) NaCl and CaCl<sub>2</sub>. (C) CsCl and CaCl<sub>2</sub>. (D) KCl and MgCl<sub>2</sub>. In both baths are 250 mM monovalent-Cl and in the luminal bath is 5 mM (■), 10 mM (□), and 50 mM (▲) divalent-Cl<sub>2</sub> or the baths contain 250 mM cytosolic monovalent-Cl and 25 mM luminal divalent-Cl<sub>2</sub> (Δ). Current/voltage curves of (E) the D4899N (■) and E4900Q (□) mutants and (F) the D4938N mutant in 250 mM symmetric KCl and 10 mM luminal CaCl<sub>2</sub>. Compared to the previous model, the current/voltage curves of Cs<sup>+</sup>/Ca<sup>2+</sup> mixtures and Na<sup>+</sup>/Ca<sup>2+</sup> mixture reproduce the data better. The data in panels A–D were first published by Chen et al. (19). The D4899N data (panel E) was previously published by Gao et al. (7), E4900Q (panel E) by Wang et al. (42), and D4938N (panel F) by Xu et al. (43).
